

Flinks Bank Connect — Simple Project Overview

For managers and non-technical readers · Demo / test overview (not a technical guide)

What is this project?

This is a **demo website** that shows how a customer can safely connect their bank account and how the business can then see basic account information (balances, account type, and so on).

1. The customer opens a secure bank-login window on the page.
2. They pick a bank and sign in (in this demo, a fake test bank).
3. After a successful connection, the page shows their account details.

No real customer money is moved. This is for **demonstration and testing only**.

Why it exists

Banks do not usually let apps ask for a username and password directly. Services like **Flinks** provide a trusted middle step so the customer logs in on a secure screen, and your app only receives permission to **view** the account information the customer agreed to share.

What you see on the screen (in order)

Step	Plain-language meaning
Consent	Customer agrees to share bank data
Institution Selection	Customer chooses their bank
Account Authentication	Customer enters username and password
Account Validation — MFA	Extra security question / check (if asked)
Account Selection	Customer picks which accounts to connect
Confirmation	Success — connection is complete

How to try the demo (test mode)

In test mode you mainly use one practice bank: **Flinks Capital**. The Flinks Dashboard may show many real bank names for design preview; this working demo focuses on Flinks Capital so login and account data can be shown safely.

Field	Value
Bank	Flinks Capital
Username	Greatday
Password	Everyday

If a security question appears, common test answers are: Montreal / Canada / Triangle / 4 (for simple math).

Sample output — what success looks like

Success! Your account is now connected.

Connected to FlinksCapital. Details from the bank connection:

Account	Number	Balance (sample)
Investments	INV00001	\$100,000.00
Chequing Account	7641238	\$5,105.50 (Available \$5,405.50)

A full Flinks Capital test run can return several accounts (chequing, savings, credit, investment-style). Each appears as its own readable card on the page.

Sample result (simple view)

Connection: Successful
Bank: Flinks Capital
Status: Account details loaded

```
[ Investments — INV00001 — $100,000.00 ]  
[ Chequing Account — 7641238 — $5,105.50 ]  
(+ other test accounts may appear)
```

What this demo does not do

- It does not transfer money.
- It does not store customer passwords.
- It does not replace a full production banking product.
- It does not connect every real bank while running in test / sandbox mode.

One-sentence summary

This project is a simple demo that connects to a test bank through Flinks and then shows readable account balances on the page — so anyone can see the customer experience without needing technical knowledge.
